SCALAR CURVATURE RIGIDITY AND RICCI DETURCK FLOW ON PERTURBATIONS OF EUCLIDEAN SPACE

ALEXANDER APPLETON

Abstract. We prove a rigidity result for non-negative scalar curvature perturbations of the Euclidean metric on $\mathbb{R}^n$, which may be regarded as a weak version of the rigidity statement of the positive mass theorem. We prove our result by analyzing long term solutions of Ricci DeTurck flow. As a byproduct in doing so, we extend known L^p bounds and decay rates for Ricci DeTurck flow and prove regularity of the flow at the initial data.

1. Introduction

In this paper we will prove the following rigidity theorem for non-negative scalar curvature metrics on $\mathbb{R}^n$:

Theorem 1.1. *There exists an $\epsilon(n) > 0$ such that any smooth metric g on $\mathbb{R}^n$, $n \geq 2$ which satisfies*

(1) $R_g \geq 0$
(2) $\|g - g_{eucl}\|_{L^\infty(\mathbb{R}^n)} < \epsilon$
(3) $\|g - g_{eucl}\|_{L^p(\mathbb{R}^n)} < \infty$ *for some* $1 \leq p < \frac{n}{n-2}$

is isometric to the standard Euclidean metric g_{eucl} on $\mathbb{R}^n$.

It is unclear what happens in the borderline case $p = \frac{n}{n-2}$ and we only have a partial result proven in lemma 6.6.

Theorem 1.1 is related to the rigidity result of the positive mass theorem proven by Schoen and Yau ([SY79a], [SY79b]). In their work they showed that the ADM-mass of an asymptotically Euclidean non-negative scalar curvature manifold (see [ADM62] and [Bar86]) of dimension $n \leq 8$, defined by

$$m(g) = \lim_{r \to \infty} \int_{S_r} (\partial_j g_{ij} - \partial_i g_{jj}) \, \mathrm{d}A^i \tag{1.1}$$

is non-negative. Furthermore they proved the rigidity statement that the manifold is flat if $m(g) = 0$. This is consistent with theorem 1.1 since for metrics satisfying $\|g - g_{eucl}\|_{L^p(\mathbb{R}^n)} < \infty$ we heuristically have

$$|g - g_{eucl}| \sim o\left(\frac{1}{r^{\frac{n}{p}}}\right)$$
$$\partial g \sim o\left(\frac{1}{r^{\frac{n}{p}-1}}\right)$$

and

$$\int_{S_r} \partial_j g_{ij} - \partial_i g_{jj} \, \mathrm{d}A^i \sim o\left(r^{n-2-\frac{n}{p}}\right)$$

Hence for $p < \frac{n}{n-2}$ we heuristically expect $m(g) = 0$ and thus g to be flat by the positive mass theorem.

We will prove theorem 1.1 by evolving the metric via the Ricci DeTurck flow, which is a geometric flow related to the Ricci flow by a time-dependent family of diffeomorphisms. Its equation can schematically be written as

$$\partial_t g_t = -2Ric(g_t) - \mathcal{L}_{X_t}(g_t), \qquad t > 0, \tag{1.2}$$

where $\mathcal{L}_{X_t}(g_t)$ is the Lie derivative of the metric g_t with respect to a time varying vector field X_t. Since we will be studying the evolution of perturbations of the Euclidean metric, it will be useful to consider the quantity $h_t = g_t - g_{eucl}$. The Ricci DeTurck equation with respect to the Euclidean background metric on $\mathbb{R}^n$ takes the form

$$(\partial_t - \Delta)h_t = Q(h_t, \nabla h_t, \nabla^2 h_t) \tag{1.3}$$

where

$$\begin{aligned} Q(h_t, \nabla h_t, \nabla^2 h_t) = (g_{eucl} + h_t)^{-1} * (g_{eucl} + h_t)^{-1} * \nabla h_t * \nabla h_t \\ + \nabla * \left(\left((g_{eucl} + h_t)^{-1} - g_{eucl}^{-1} \right) * \nabla h \right) \end{aligned}$$

Equation (1.3) is strongly parabolic, however due to its non-linearity and the non-compactness of the domain, a short time solution does not exist a priori and if one does, we expect singularities to develop after finite time. Surprisingly it turns out that for L^∞-small initial data a long time solution to the flow exists.

Schnürer, Schulze and Simon in [SSS08] were the first to show long time existence to the Ricci DeTurck equation (1.3) for C^0 perturbations of the Euclidean metric, which satisfy certain L^∞-decay conditions at infinity. In their paper they also prove that perturbations bounded in L^p for $p \geq 2$ remain bounded at later times. Using this and an interpolation inequality, they proved corresponding long term L^∞-decay rates of h_t. We will extend their results to $1 \leq p < 2$ and slightly improve their decay rates using a limit argument (see our theorem 1.2, (ii) & (iii)).

Koch and Lamm in [KL12] were able to remove the decay conditions at infinity by constructing a weak solution and proving analyticity of the solution on $\mathbb{R}^n \times (0, \infty)$. We will make extensive use of the results of Koch and Lamm and extend them by showing that the weak solution they constructed is classical, e.g. the solution and its derivatives are continuous up to $t = 0$, if the initial data is regular. In particular we prove the following theorem:

Theorem 1.2. *There exists an $\epsilon = \epsilon(n) > 0$ and $C = C(n) > 0$ such that for smooth initial data h_0 satisfying $\|h_0\|_{L^\infty(\mathbb{R}^n)} < \epsilon$ we have*

(i) A smooth classical solution $h_t \in C^\infty(\mathbb{R}^n \times [0, \infty))$ to the Ricci DeTurck equation (1.3) exists.

(ii) If $\|h_0\|_{L^p(\mathbb{R}^n)} < \infty$ for some $1 \leq p \leq \infty$, then $\|h_t\|_{L^p(\mathbb{R}^n)} \leq C \|h_0\|_{L^p(\mathbb{R}^n)}$ for all $t \geq 0$.

(iii) If $\|h_0\|_{L^p(\mathbb{R}^n)} < \infty$ for some $1 \leq p < \infty$, then the following decay rate holds for $t > 0$

$$\sup_{x \in \mathbb{R}^n} |h_t(x)| \leq \frac{C}{t^{\frac{n}{2p}}} \|h_0\|_{L^p(\mathbb{R}^n)}. \tag{1.4}$$

For higher derivatives we have that there exists a $R = R(n) > 0$ such that for all $k \in \mathbb{N}_0$ and multiindexes $\alpha \in \mathbb{N}_0^n$ we have

$$\sup_{x\in\mathbb{R}^n} |(t^{\frac{1}{2}}\nabla)^\alpha (t\partial_t)^k h_t(x)| \leq \frac{CR^{|\alpha|+k}(|\alpha|+k)!}{t^{\frac{n}{2p}}} \|h_0\|_{L^p(\mathbb{R}^n)}. \tag{1.5}$$

The setup of our paper is as follows: We will begin by proving that a classical solution to the Ricci DeTurck equation exists for sufficiently regular initial data. Then we will show that initial data bounded in $L^p(\mathbb{R}^n)$, for some $1 \leq p < \infty$ remains uniformly bounded in $L^p(\mathbb{R}^n)$ at later times. This will allow us to prove L^∞ decay rates of the evolving metric and its derivatives, which are as one would expect from the standard heat equation on $\mathbb{R}^n$.

Ultimately, we will use the decay rates on the metric and its derivatives to prove the scalar rigidity theorem 1.1 above. The scalar curvature under Ricci DeTurck flow satisfies the following super heat equation

$$(\partial_t - \Delta + \mathcal{L}_{X_t})R(g_t) = 2|Ric(g_t)|^2. \tag{1.6}$$

By comparison with the standard heat equation on $\mathbb{R}^n$ we expect the scalar curvature to decay at a rate no faster than $O(t^{-\frac{n}{2}})$. In conjunction with above decay rates on the metric this will lead to a contradiction for $p < \frac{n}{n-2}$, which will allow us to prove theorem 1.1. For the borderline case $p = \frac{n}{n-2}$, we will show in lemma 6.6 that the L^1 norm of the scalar curvature $R(g_t)$ becomes bounded at times $t > 0$.

2. Notation

If not specified otherwise, we will take norms and derivatives with respect to the fixed Euclidean background metric g_{eucl}, e.g. ∇ will denote the covariant derivative with respect to g_{eucl}.

For two metrics g and $\overline{g}$ we say $g \leq \overline{g}$ if for all $\xi \in \mathbb{R}^n$ we have

$$g_{ij}\xi^i\xi^j \leq \overline{g}_{ij}\xi^i\xi^j$$

We define a standard cut-off function η on $\mathbb{R}^n$, such that $\eta, \nabla\sqrt{\eta} \in C_c^\infty(B_2(0))$, $0 \leq \eta \leq 1$, $\eta \equiv 1$ on $B_1(0)$ and $\|\nabla\eta\| \leq c$ for some universal c .We also define a rescaled cut-off function $\eta_R(y) = \eta(\frac{y}{R})$ for $R > 0$. By $\eta_{R,x}$ we will denote the rescaled cut-off function centered at x, defined by $\eta_{R,x}(y) = \eta(\frac{x-y}{R})$.

3. Preliminaries

3.1. **Ricci DeTurck flow.** Given a manifold M one fixes a time-independent background metric $\overline{g}$. Then a family of metrics $(g_t)_{t\in I}$ are a solution of the Ricci DeTurck flow if they satisfy the following equation

$$\partial_t g_t = -2\mathrm{Ric}_{g_t} - \mathcal{L}_{X_{\overline{g}}(g_t-\overline{g})}(g_t), \tag{3.1}$$

where $X_{\overline{g}}(h)$ is the Bianchi operator defined on symmetric 2-forms h by

$$X^i_{\overline{g}}(h) = (\overline{g}+h)^{ij}(\overline{g}+h)^{pq}\left(-\nabla^{\overline{g}}_p h_{qj} + \frac{1}{2}\nabla^{\overline{g}}_j h_{pq}\right) \tag{3.2}$$

and the covariant derivatives are taken with respect to $\overline{g}$. One can check that this equation is strongly parabolic, allowing standard parabolic theory to be applied to show short time existence on closed manifolds. We will only be considering Ricci DeTurck flow on $\mathbb{R}^n$ with the standard Euclidean metric $\overline{g} = g_{eucl}$ as the fixed

background metric. Then the Ricci DeTurck equation takes the form (see [SSS08, Section 3])

$$\begin{aligned}\partial_t g_{ij} &= g^{ab}\nabla_a\nabla_b g_{ij} \\ &\quad + \frac{1}{2}g^{ab}g^{pq}\big(\nabla_i g_{pa}\nabla_j g_{qb} + 2\nabla_a g_{jp}\nabla_q g_{ib} + 2\nabla_a g_{jp}\nabla_b g_{iq} \\ &\qquad - 2\nabla_j g_{pa}\nabla_b g_{iq} - 2\nabla_i g_{pa}\nabla_b g_{jq}\big).\end{aligned} \tag{3.3}$$

We will write $X(h)$ for the Bianchi Operator on the Euclidean background. It will be useful to consider the difference $h := g_t - g_{eucl}$. Using the above equation we can express the evolution of h in the following form (see [KL12, Theorem 4.4]):

$$(\partial_t - \Delta)h = Q_0[h] + \nabla Q_1[h] \tag{3.4}$$

where

$$\begin{aligned}Q_0[h] = \frac{1}{2}(\delta+h)^{ab}(\delta+h)^{pq}\Big(&\nabla_i h_{pa}\nabla_j h_{qb} + 2\nabla_a h_{jp}\nabla_q h_{ib} - 2\nabla_a h_{jp}\nabla_b h_{iq} \\ &- 2\nabla_j h_{pa}\nabla_b h_{iq} - 2\nabla_i h_{pa}\nabla_b h_{jq}\Big) - \nabla_a(\delta+h)^{ab}\nabla_b h_{ij}\end{aligned} \tag{3.5}$$

and

$$\nabla Q_1[h] = \nabla_a\left((\delta+h)^{ab} - \delta^{ab})\nabla_b h_{ij}\right) \tag{3.6}$$

3.2. **Long time existence of Ricci DeTurck flow.** In [KL12, Theorem 4.3] Koch and Lamm prove existence of a long time weak solution to the Ricci DeTurck equation (3.4). Using Duhamel's Principle they rewrite the Ricci DeTurck equation (3.4) in integral form

$$h = F[h, h_0] = S[h_0] + V[h], \tag{3.7}$$

where

$$\begin{aligned}S[h_0](x,t) &= \int_{\mathbb{R}^n} K(x,t;y,0)h_0(y)\,\mathrm{d}y \\ V[h](x,t) &= \int_0^t\int_{\mathbb{R}^n} K(x,t;y,s)Q_0[h] + \nabla_x K(x,t;y,s)Q_1[h]\,\mathrm{d}y\,\mathrm{d}s\end{aligned}$$

and $K(x,t;y,s) = (4\pi(t-s))^{-\frac{n}{2}}\exp(-\frac{|x-y|^2}{4(t-s)})$ is the kernel of the linear heat equation $\partial_t u = \Delta u$ on $\mathbb{R}^n$. Koch and Lamm construct a Banach space X_∞ for which $F[\cdot, h_0]$ is a contraction map provided $\|h_0\|_{L^\infty(\mathbb{R}^n)} < \epsilon$, where $\epsilon = \epsilon(n)$ is a constant depending on n only. This proves existence of a solution h_t to the weak Ricci DeTurck equation (3.7) above for small initial data. They then prove that this weak solution is analytic in $\mathbb{R}^n \times (0,\infty)$ and that the following decay rates hold for every multiindex $\alpha \in \mathbb{N}_0^n$ and $k \in \mathbb{N}_0$

$$\sup_{x\in\mathbb{R}^n}\sup_{t>0}|(t^{\frac{1}{2}}\nabla)^\alpha(t\partial_t)^k h(x,t)| \leq C\,\|h_0\|_{L^\infty(\mathbb{R}^n)}\,R^{|\alpha|+k}(|\alpha|+k)!, \tag{3.8}$$

where $R = R(n)$, $C = C(n)$ are constants depending on n only.

In this paper we will prove regularity of the weak solution h_t up to $t = 0$, i.e. for smooth initial data we have h_t and its derivatives are continuous on $\mathbb{R}^n \times [0,\infty)$.

3.3. **Ricci Flow and long time existence.** A family of time dependent metrics $(\tilde{g}_t)_{t\geq 0}$ is a solution to the Ricci flow equations if

$$\partial_t \tilde{g}_t = -2Ric(\tilde{g}_t), \quad t \geq 0. \tag{3.9}$$

Ricci and Ricci DeTurck flow are related by a family of time dependent diffeomorphisms (see [Top06] for details): Assume that $(g_t)_{t\geq 0}$ is a solution to the Ricci DeTurck equation (3.3) and the family of time dependent diffeomorphisms Φ_t generated by the vector field $X(g_t)$ (see (3.2))

$$\partial_t \Phi_t = X(g_t)(\Phi_t), \quad t \geq 0 \tag{3.10}$$

$$\Phi_0 = id \tag{3.11}$$

exists, then the pullback $\tilde{g}_t = \Phi_t^* g_t$ is a solution to the Ricci flow equation (3.9). In [SSS08, Lemma 9.1] it was shown that this family of diffeomorphisms $\Phi_t \in C^\infty(\mathbb{R}^n \times [0,\infty))$ exists, when $g_t \in C^\infty(\mathbb{R}^n \times [0,\infty))$ and the decay rates (3.8) hold.

4. Regularity of weak solution

In this section we will study the behavior at $t = 0$ of the weak solution h_t to the Ricci DeTurck equation constructed in [KL12, Theorem 4.3]. Our main goal will be to prove the following theorem:

Theorem 4.1. *There exists an $\epsilon = \epsilon(n) > 0$ such that for smooth initial data $h_0 \in C^\infty(\mathbb{R}^n)$ satisfying $\|h_0\|_{L^\infty(\mathbb{R}^n)} \leq \epsilon$, a classical smooth solution $h_t \in C^\infty(\mathbb{R}^n \times [0,\infty))$ to the Ricci DeTurck equation (3.4) exists.*

The first step will be to prove that the weak solution is classical and smooth for smooth initial data of compact support. Approximating our intial data by compactly supported functions, we will then prove $C^{2,1}$ regularity of h_t. The main difficulty at this step will be to prove a local boundary estimate using standard parabolic Hölder estimates, which allows us to pass to the limit via Arzelà–Ascoli and a diagonal argument. In the final step we will bootstrap our boundary estimate to show that the solution h_t and its derivatives are continuous up to $t = 0$.

Below we begin by proving the compact case.

Lemma 4.2. *There exists an $\epsilon = \epsilon(n) > 0$ such that for $h_0 \in C_c^\infty(\mathbb{R}^n)$ satisfying $\|h_0\|_{L^\infty(\mathbb{R}^n)} < \epsilon$ the weak solution h_t is classical and smooth on $\mathbb{R}^n \times [0,\infty)$.*

Proof. In [KL12, Theorem 4.3] an analytical operator

$$A : B_\epsilon(0) \subset C^0(\mathbb{R}^n) \longrightarrow X_\infty \tag{4.1}$$

was constructed for sufficiently small $\epsilon = \epsilon(n) > 0$ such that $A(h_0) \in X_\infty$ is a weak solution to (3.7) for $\|h_0\|_{L^\infty(\mathbb{R}^n)} < \epsilon$. Because the operator A is analytic, we can choose $\epsilon > 0$ sufficiently small such that

$$\left\|A(h_0^1) - A(h_0^2)\right\|_{X_\infty} \leq C_1 \left\|h_0^1 - h_1^2\right\|_{C^0(\mathbb{R}^n)} \tag{4.2}$$

for $h_0^1, h_0^2 \in B_\epsilon(0) \subset C^0(R^n)$ and $C_1 = C_1(\epsilon)$ a constant. Inspecting the norm on X_∞ we then see that

$$\sup_{0<t<\infty} \left\|h_t^1 - h_t^2\right\|_{L^\infty(\mathbb{R}^n)} \leq C_1 \left\|h_0^1 - h_1^2\right\|_{L^\infty(\mathbb{R}^n)}, \tag{4.3}$$

where we wrote $h_t^i = A(h_0^i)(\cdot, t)$ for $i = 1, 2$. Thus for initial data $h_0 \in C_c^\infty(\mathbb{R}^n)$ we see that the difference quotients of h_t are uniformly bounded and therefore $|\nabla h_t|$ is

uniformly bounded. Similarly we obtain that higher derivatives of h_t are uniformly bounded as well. Recalling that the weak solution h_t satisfies

$$h_t = \int_{\mathbb{R}^n} K(x,t,y,0)h_0(y)\,\mathrm{d}y + \int_0^t \int_{\mathbb{R}^n} K(x,t,y,s)Q_0[h](y,s) + \nabla_x K(x,t,y,s)Q_1[h](y,s)\,\mathrm{d}y\mathrm{d}s$$

we can use the uniform derivative bounds to show that $|\nabla^i h_t| \to |\nabla^i h_0|$ locally uniformly for $t \to 0$. Similary we can prove that the time derivatives and mixed time and spatial derivatives are continuous up to the boundary. □

We will now prove an a priori local boundary Hölder estimate for h_t. Our arguments closely follow those presented in [Bam14, Prof. 2.5] where the corresponding interior estimates were derived. This estimate will allow us to approximate non-compact, locally Hölder-regular initial data by a sequence of compactly supported smooth initial data and show that the corresponding solutions converge in a local Hölder sense.

Let us fix some notation first. If $\Omega \subset \mathbb{R}^n \times \mathbb{R}$ is some parabolic neighbourhood (e.g. $\Omega = B_r(0) \times (0, r^2)$)) we denote by $C^{2m,m}(\Omega)$ the space of functions differentiable i times in the spatial direction and j times in the time direction as long as $i + 2j \leq 2m$. For $\alpha \in (0, \frac{1}{2})$ the corresponding Hölder space will be denoted by $C^{2m,2\alpha;m,\alpha}(\Omega)$. Greek letters will always refer to the Hölder exponent. In the following we will use weighted Hölder norms on $C^{2m,2\alpha;m,\alpha}(\Omega)$, which are invariant under parabolic dilations: Assume

$$r_\Omega = \min(r : \Omega \subset B_r(p) \times [t - r^2, t] \text{ for some } p, t) < \infty \tag{4.4}$$

then

$$\|u\|_{C^{2m,2\alpha;m,\alpha}(\Omega)} = \sum_{|\iota|+2k\leq 2m} r_\Omega^{|\iota|+2k} \left(\left\| \nabla^\iota \partial_t^k u \right\|_{C^0} + r_\Omega^{2\alpha} [\nabla^\iota \partial_t^k u]_{2\alpha,\alpha} \right) \tag{4.5}$$

When $m = 0$ we will write $\|u\|_{C^{2\alpha;\alpha}(\Omega)} := \|u\|_{C^{0,2\alpha;0,\alpha}(\Omega)}$ for brevity.

By L we will denote a second order elliptic operator with real coefficients and constant of ellipticity $\kappa > 0$ of the form $L(x,t) = a^{ij}(x,t)\partial_i\partial_j + b^i(x,t)\partial_i + c(x,t)$.

For $z = (x,t) \in \mathbb{R}^{n+1}$ we will denote by $Q_r(z)$ the parabolic neighborhood $B_r(x) \times (t - r^2, t) \subset \mathbb{R}^{n+1}$.

Now we recall an a priori estimate for the linear parabolic initial value problem.

Lemma 4.3. *Let $\Omega = \mathbb{R}^n \times (0, \infty)$ and fix $z = (x_0, t_0) \in \mathbb{R}^{n+1}$. Assume that $\|a, b, c\|_{C^{2\alpha;\alpha}(\Omega_{2r}(z)\cap\Omega)} \leq K$, $u \in C^{2,2\alpha;1,\alpha}(\Omega_{2r}(z) \cap \Omega)$, $f \in C^{2\alpha;\alpha}(\Omega_{2r}(z) \cap \Omega)$ and $u_0 \in C^{2,\alpha}(B_{2r}(x_0))$. If u solves the parabolic equation*

$$\partial_t u - Lu = f, \qquad \text{on } \Omega_{2r}(z) \cap \Omega, \tag{4.6}$$

$$u(\cdot, 0) = u_0, \qquad \text{on } \Omega_{2r}(z) \cap \partial\Omega, \tag{4.7}$$

then we have the boundary estimate

$$\|u\|_{C^{2,2\alpha;1,\alpha}(\Omega_r(z)\cap\Omega)} \leq C\Big(r^2 \|f\|_{C^{2\alpha;\alpha}(\Omega_{2r}(z)\cap\Omega)} + \|u\|_{C^0(\Omega_{2r}(z)\cap\Omega)} + \|u_0\|_{C^{2,2\alpha}(B_{2r}(x_0))} \Big), \tag{4.8}$$

where C is a constant that depends on α, n, κ and K.

Proof. By scale invariance we can assume without loss of generality $r = 1$. Then the result follows from [KYL96, Exercise 9.2.5] applied to $u - u_0$ and [KYL96, Remark 8.11.2]. □

We now use above lemma 4.3 to prove the main estimate of the section.

Lemma 4.4. *Fix $r > 0$ and $\alpha \in (0, \frac{1}{2})$. Consider the parabolic neighborhoods $\Omega_r = B_r \times (0, r^2) \subset \Omega'_{2r} = B_{2r} \times (0, r^2)$ and assume that $u \in C^{2,2\alpha;1,\alpha}(\Omega'_{2r})$ satisfies the equation*

$$(\partial_t - \Delta)u = Q[u] = f_1(r^{-1}x, u) \cdot \nabla u \otimes \nabla u + f_2(r^{-1}x, u) \cdot u \otimes \nabla^2 u \tag{4.9}$$

$$u(\cdot, 0) = u_0, \tag{4.10}$$

where f_1, f_2 are smooth vector-valued functions in x and u and f_1, f_2 can be paired with tensors $\nabla \otimes \nabla$ and $u \otimes \nabla^2 u$ respectively. Then there are constants $\epsilon' > 0$ and $C' < \infty$ depending only on α, n and the f_i such that if

$$H = \|u\|_{L^\infty(\Omega'_{2r})} + \|u_0\|_{C^{2,2\alpha}(B_{2r})} < \epsilon', \tag{4.11}$$

then

$$\|u\|_{C^{2,2\alpha;1,\alpha}(\Omega_r)} < C'H. \tag{4.12}$$

Moreover, the lemma still holds if u is vector-valued.

Proof. We will adapt the proof of [Bam14, Prop. 2.5] to the boundary case. We begin by introducing a new weighted norm for $0 < \theta \leq 1$ and Ω a parabolic neighbourhood:

$$\|u\|^{(\theta)}_{C^{2m,2\alpha;m,\alpha}(\Omega)} = \sum_{|\iota|+2k\leq 2m} (r_\Omega \theta)^{|\iota|+2k} \left(\left\| \nabla^\iota \partial_t^k u \right\|_{C^0} + (r_\Omega \theta)^{2\alpha} [\nabla^\iota \partial_t^k u]_{2\alpha,\alpha} \right), \tag{4.13}$$

For $\theta = 1$, this norm agrees with the norm defined above. We also introduce a weighted norm on $C^{2m,2\alpha}(\mathbb{R}^n)$ in an analogous way. Choosing any $z = (x, t) \in R^n \times (0, r^2)$ such that $B_{\theta r}(x) \subset B_r$ and applying lemma 4.3 on $Q_{\theta r}(z)$ we deduce

Assume we are in the setting of lemma 4.3, then

$$\begin{aligned} \|u\|^{(\theta)}_{C^{2,2\alpha;1,\alpha}(\Omega_r)} \leq C\Big(& (r\theta)^2 \|f\|^{(\theta)}_{C^{2\alpha;\alpha}(B_{(1+\theta)r}\times(0,r^2))} \\ & + \|u\|^{(\theta)}_{C^0(B_{(1+\theta)r}\times(0,r^2))} + \|u_0\|^{(\theta)}_{C^{2,2\alpha}(B_{(1+\theta)r})} \Big) \end{aligned} \tag{4.14}$$

In the following we may assume by scaling invariance that $r = 1$ and we will abbreviate by C any constant that depends on n, α and f_i, $i = 1, 2$. Set $r_k = \sum_{i=0}^k 2^{-i} = 2 - 2^{-k}$, $\theta_k = \frac{r_{k+1}}{r_k} - 1$ and $\Omega_k = B_{r_k}(0) \times [0, 1]$.

By (4.14) for $r = r_k$ we have

$$a_k := \|u\|^{(\theta_k)}_{C^{2,2\alpha;1,\alpha}(\Omega_k)} \leq C \left(\theta_k^2 \|Q[u]\|_{C^{2\alpha;\alpha}(\Omega_{k+1})} + H \right). \tag{4.15}$$

Observe that since $\theta_k \to 0$, we have $a_k \to a_\infty = \|u\|_{C^0(\Omega')} \leq H$. We now estimate $Q[u]$ in terms of u using (4.9). For this note that for $i = 1, 2$

$$\|f_i(x, u)\|^{(\theta_{k+1})}_{C^{2\alpha;\alpha}(\Omega_{k+1})} \leq C \left(1 + \|u\|^{(\theta_{k+1})}_{C^{2\alpha;\alpha}(\Omega_{k+1})} \right) \leq C(1 + a_{k+1}) \tag{4.16}$$

So we obtain

$$\begin{aligned}\|f_1 \cdot \nabla u \otimes \nabla u\|^{(\theta_{k+1})}_{C^{2\alpha;\alpha}(\Omega_{k+1})} &\leq \|f_1\|^{(\theta_{k+1})}_{C^{2\alpha;\alpha}(\Omega_{k+1})} \left(\|\nabla u\|^{(\theta_{k+1})}_{C^{2\alpha;\alpha}(\Omega_{k+1})}\right)^2 \\ &\leq C\theta_{k+1}^{-2}\left(a_{k+1}^2 + a_{k+1}^3\right) \end{aligned} \tag{4.17}$$

Similarly we have

$$\left\|f_2 \cdot u \otimes \nabla^2 u\right\|^{(\theta_{k+1})}_{C^{2\alpha;\alpha}(\Omega_{k+1})} \leq C\theta_{k+1}^{-2}\left(a_{k+1}^2 + a_{k+1}^3\right). \tag{4.18}$$

We conclude

$$\|Q[u]\|^{(\theta_{k+1})}_{C^{2\alpha;\alpha}(\Omega_{k+1})} \leq C\theta_{k+1}^{-2}\left(a_{k+1}^2 + a_{k+1}^3\right). \tag{4.19}$$

Hence

$$a_k \leq C(a_{k+1}^2 + a_{k+1}^3 + H) \tag{4.20}$$

Therefore the quantity $b_k = \frac{a_k}{H}$ satisfies the inequality

$$b_k \leq C(Hb_{k+1}^2 + H^2 b_{k+1}^3 + 1). \tag{4.21}$$

Assuming without loss of generality that $C > 1$ and setting $\epsilon' = \frac{1}{16C^2}$ we see that

$$b_k \leq \frac{b_{k+1}^2}{16C} + \frac{b_{k+1}^3}{16^2C^3} + C, \tag{4.22}$$

because we assumed that $H \leq \epsilon'$. From this we see that if $b_{k+1} \leq 2C$ then $b_k \leq 2C$ as well. Since $b_k \to \frac{a_\infty}{H} \leq 1 \leq 2C$ as $k \to \infty$ we conclude that $b_0 \leq 2C$ and thus $a_0 \leq 2CH$. □

Using above lemma we can now proceed to proving $C^{2,2\alpha;1,\alpha}$-regularity.

Theorem 4.5. *Fix an $\alpha \in (0, \frac{1}{2})$. Then there exists an $\epsilon > 0$ such that for any $h_0 \in C^{2,2\alpha}_{loc}(\mathbb{R}^n)$ and $\|h_0\|_{L^\infty(\mathbb{R}^n)} \leq \epsilon$ the weak solution h_t of the Ricci DeTurck equation (3.4) constructed in* [KL12, Theorem 4.3] *is classical. In particular for any relatively compact open set $\Omega \subset\subset \mathbb{R}^n \times [0, \infty)$ we have $h_t \in C^{2,2\alpha;1,\alpha}(\Omega)$.*

Proof of the Theorem 4.5. Choose $\epsilon' > 0$ as in lemma 4.4 above. Then choose $\epsilon > 0$ such that a weak solution u_t to the Ricci DeTurck equation (3.4) exists for initial data u_0 satisfying $\|u_0\|_{L^\infty(\mathbb{R}^n)} < \epsilon$. By choosing ϵ sufficiently small we may assume that $\|u_t\|_{L^\infty(\mathbb{R}^n)} \leq \frac{1}{3}\epsilon'$ uniformly for $t \geq 0$ (see [KL12, theorem 4.3]). Take a sequence $u_0^i \in C_c^\infty(\mathbb{R}^n)$, $i = 1, 2, 3, \cdots$ satisfying $\left\|u_0^i\right\|_{L^\infty(\mathbb{R}^n)} \leq \epsilon$, which locally converges to u_0 in $C^{2,2\alpha}_{loc}(\mathbb{R}^n)$ as $i \to \infty$. By lemma 4.2 a smooth solution u_t^i to the Ricci DeTurck equation (3.4) with initial data u_0^i exists for all $i \in \mathbb{N}$. For each $x \in \mathbb{R}^n$ we can then choose an $r_x > 0$ such that the quantity H of lemma 4.4 is less than $\frac{5}{6}\epsilon'$. Thus we can choose countable many points $(x_i)_{i\in\mathbb{N}} \in \mathbb{R}^n$ such that $\mathbb{R}^n \times \{t = 0\}$ is covered by sets of the form $\Omega_i = B_{r_{x_i}}(x_i) \times [0, r_{x_i}^2)$ on which (4.12) holds for all u_0^i satisfying $\left\|u_0^i - u_0\right\|_{C^{2,2\alpha}(\Omega_i)} \leq \frac{1}{6}\epsilon'$. Note that by [KL12, theorem 4.3] we know that on any compactly supported open set $\Omega \subset\subset \mathbb{R}^n \times (0, \infty)$ we have uniform bounds of the form $\left\|u_t^i\right\|_{C^{2,2\alpha;1,\alpha}(\Omega)} \leq C(\Omega)$. Thus, by Arzela-Ascoli and a diagonal argument we can pass to a limit giving us the desired result. □

Remark 4.6. Using similar arguments we can show that if we start with continuous initial data $u_0 \in C^0(\mathbb{R}^n)$, the corresponding weak solution is continuous up to the boundary: Take $u_0^i \in C^{2,2\alpha}(\mathbb{R}^n)$ converging uniformly to u_0 in $C^0(\mathbb{R}^n)$ and use the estimate (4.3) to prove convergence.

Now we can prove theorem 4.1.

Proof of theorem 4.1. Choose $\epsilon > 0$ such that above theorem 4.5 applies and thus $h \in C^{2,2\alpha;1,\alpha}_{loc}(\mathbb{R}^n \times [0,\infty))$. We can then write the Ricci DeTurck equation (3.3) in the form

$$\partial_t h - (g_{eucl} + h)^{ab}\nabla_a \nabla_b h = f(x,h) * \nabla h * \nabla h, \tag{4.23}$$

for f a smooth vector-valued function. The upshot is that the righthand side is of lower order than the lefthand side, allowing us to bootstrap [KYL96, theorem 8.12.1 & exercise 8.12.4] to prove that h is smooth. □

Remark 4.7. Strictly speaking [KYL96, theorem 8.12.1 & exercise 8.12.4] only apply to proving interior regularity. However, one can check using lemma 4.3 that they can easily be adapted to hold in the boundary case.

5. L^p bounds and L^∞-decay rates for Ricci DeTurck Flow

5.1. **L^p bounds.** In the following we will show that a solution h_t to the Ricci DeTurck equations with initial data h_0 bounded in $L^p(\mathbb{R}^n)$ for some $1 \leq p < \infty$ remains bounded in L^p provided the initial data is sufficiently small in $L^\infty(\mathbb{R}^n)$. In particular we will prove the following theorem:

Theorem 5.1. *There exist constants $\tilde{\epsilon} = \tilde{\epsilon}(n) > 0$ and $\tilde{C} = \tilde{C}(n) > 0$ such that the following holds: Given a solution $h_t \in C^{2,1}(\mathbb{R}^n \times [0,\infty))$ to the Ricci DeTurck equation (3.4) satisfying (i) $\|h_t\|_{L^\infty(\mathbb{R}^n \times (0,\infty))} < \tilde{\epsilon}$ and (ii) $\|h_0\|_{L^p(\mathbb{R}^n)} < \infty$ for some $1 \leq p < \infty$ we have the estimate*

$$\|h_t\|_{L^p(\mathbb{R}^n)} \leq \tilde{C}\,\|h_0\|_{L^p(\mathbb{R}^n)}, \quad t \geq 0. \tag{5.1}$$

If $p \geq 2$ we can take $\tilde{C} = 1$.

Remark 5.2.

(1) By applying estimate (3.8) we can relax condition (i) to $\|h_0\|_{L^\infty(\mathbb{R}^n))} < \tilde{\epsilon}$ by choosing $\tilde{\epsilon}$ sufficiently small.
(2) The result is as one would expect by comparison with the linear heat equation on $\mathbb{R}^n$.

The strategy to prove this theorem will be to find local L^p estimates for the solution h_t and integrate these to global ones using Grönwall's Lemma. For technical reasons we will first prove the result for $2 \leq p < \infty$. As a byproduct of this result we will find an $L^2(\mathbb{R}^n \times (0,\infty))$ bound on ∇h, which will allow us to generalize to the $1 \leq p < 2$ case. Below we state our first local L^p bound.

Lemma 5.3. *There exist constants $\tilde{\epsilon} > 0$ and $C_1 > 0$ such that for a solution $h \in C^{2,1}(\mathbb{R}^n \times [0,\infty))$ with $\|h\|_{L^\infty(\mathbb{R}^n \times [0,\infty))} < \tilde{\epsilon}$ to the Ricci DeTurck equation (3.4) the following estimate holds in the barrier sense for $2 \leq p < \infty$*

$$\partial_t \int_{\mathbb{R}^n} \eta_R |h|^p \,\mathrm{d}x \leq \frac{C_1(1+p)}{R^2} \int_{B_{2R}\setminus B_R} |h|^p \,\mathrm{d}x. \tag{5.2}$$

Proof. In the following we will denote by C any constant depending on n and η only. We will also assume $\tilde{\epsilon} < \frac{1}{2}$. Let $\delta > 0$ and define

$$|h|_\delta = \sqrt{\langle h, h\rangle + \delta}$$

Then $|h|_\delta \in C^{2,1}(\mathbb{R}^n \times (0,\infty))$, $|h|_\delta \geq \delta$, $|h|_\delta > |h|$ and $|h|_\delta \to |h|$ pointwise as $\delta \to 0$. A simple calculation shows

$$\Delta |h|_\delta^p = p(p-2)|h|_\delta^{p-4}\langle \nabla_a h, h\rangle \langle \nabla_a h, h\rangle + p|h|_\delta^{p-2}\left(\langle \nabla h, \nabla h\rangle + \langle \Delta h, h\rangle\right), \tag{5.3}$$

where we sum over equal indices. Since h satisfies the Ricci DeTurck equation (3.4) we obtain

$$\partial_t |h|_\delta^p = p|h|_\delta^{p-2}\langle \Delta h, h\rangle + p|h|_\delta^{p-2}\langle Q[h], h\rangle \tag{5.4}$$

$$= \Delta |h|_\delta^p - p|h|_\delta^{p-2}|\nabla h|^2 + p(2-p)|h|_\delta^{p-4}\langle \nabla_a h, h\rangle \langle \nabla_a h, h\rangle + p|h|_\delta^{p-2}\langle Q_0[h] + \nabla Q_1[h], h\rangle, \tag{5.5}$$

Therefore multiplying (5.5) by η_R, integrating over $\mathbb{R}^n$ and discarding boundary terms we obtain

$$\partial_t \int_{\mathbb{R}^n} \eta_R |h|_\delta^p \,\mathrm{d}x = \int_{\mathbb{R}^n} \Delta \eta_R |h|_\delta^p - \eta_R p|h|_\delta^{p-2}|\nabla h|^2 + \eta_R p(2-p)|h|_\delta^{p-4}\langle \nabla_a h, h\rangle \langle \nabla_a h, h\rangle + p\eta_R |h|_\delta^{p-2}\langle Q_0[h] + \nabla Q_1[h], h\rangle \,\mathrm{d}x. \tag{5.6}$$

Recalling the definitions of $Q_0[h]$ and $Q_1[h]$ in (3.5) and (3.6) respectively we see that

$$Q_0[h] = (g_{eucl} + h)^{-1} * (g_{eucl} + h)^{-1} * \nabla h * \nabla h \tag{5.7}$$

$$Q_1[h]^a_{ij} = \left((g_{eucl} + h)^{ab} - g^{ab}_{eucl}\right) \nabla_b h_{ij} \tag{5.8}$$

By assumption $\|h\|_{L^\infty(\mathbb{R}^n \times [0,T])} < \frac{1}{2}$, so

$$|Q_0[h]| \leq C|\nabla h|^2 \tag{5.9}$$

$$|Q_1[h]| \leq C|h||\nabla h| \tag{5.10}$$

Thus by Cauchy Schwarz and integration by parts we have

$$\partial_t \int_{\mathbb{R}^n} \eta_R |h|_\delta^p \,\mathrm{d}x \leq \int_{\mathbb{R}^n} \Delta \eta_R |h|_\delta^p + p(C\tilde{\epsilon} - 1)\eta_R p|h|_\delta^{p-2}|\nabla h|^2 + \eta_R p(2-p)|h|_\delta^{p-4}\langle \nabla_a h, h\rangle \langle \nabla_a h, h\rangle - pQ_1[h]^a_{ij}\nabla_a \left(h_{ij}\eta_R |h|_\delta^{p-2}\right) \,\mathrm{d}x \tag{5.11}$$

Focussing on the last term in the integrand above we have

(5.12)

$$\begin{aligned}\int_{\mathbb{R}^n} -pQ_1[h]^a_{ij}\nabla_a\left(h_{ij}\eta_R|h|_\delta^{p-2}\right)\,\mathrm{d}x &\le \int_{\mathbb{R}^n} p|Q_1[h]|\left(|\nabla h|\eta_R|h|_\delta^{p-2}+|h||\nabla\eta_R||h|_\delta^{p-2}\right)\\ &\qquad - pQ_1[h]^a_{ij}h_{ij}\eta_R\nabla_a|h|_\delta^{p-2}\,\mathrm{d}x\\ &\le \int_{\mathbb{R}^n} Cp\eta_R|h||h|_\delta^{p-2}|\nabla h|^2+Cp|\nabla\eta_R||h|^2|h|_\delta^{p-2}|\nabla h|\\ &\qquad - \eta_R p(p-2)|h|_\delta^{p-4}\langle\nabla_a h,h\rangle\left((g_{eucl}+h)^{ab}-g_{eucl}^{ab}\right)\langle\nabla_b h,h\rangle\,\mathrm{d}x \qquad (5.13)\\ &\le \int_{\mathbb{R}^n} Cp\tilde{\epsilon}\eta_R|h|_\delta^{p-2}|\nabla h|^2+Cp|\nabla\eta_R||h|^2|h|_\delta^{p-2}|\nabla h|\\ &\qquad + \eta_R p(p-2)|h|_\delta^{p-4}\langle\nabla_a h,h\rangle\langle\nabla_a h,h\rangle\,\mathrm{d}x\\ &\le \int_{\mathbb{R}^n} Cp\tilde{\epsilon}\eta_R|h|_\delta^{p-2}|\nabla h|^2+Cp\tilde{\epsilon}\left(\nabla\sqrt{\eta_R}\right)^2|h|_\delta^p\\ &\qquad + \eta_R p(p-2)|h|_\delta^{p-4}\langle\nabla_a h,h\rangle\langle\nabla_a h,h\rangle\,\mathrm{d}x,\end{aligned}$$

where in the last step we used Young's inequality to estimate

$$\begin{aligned}|\nabla\eta_R||h|^2|h|_\delta^{p-2}|\nabla h| &= \eta_R^{\frac{1}{2}}|\nabla h||h|^{\frac{1}{2}}|h|_\delta^{\frac{p-2}{2}}\cdot\left(\frac{|\nabla\eta_R|}{\eta_R^{\frac{1}{2}}}\right)|h|^{\frac{3}{2}}|h|_\delta^{\frac{p-2}{2}} \qquad (5.14)\\ &\le \frac{1}{2}\eta_R|\nabla h|^2|h||h|_\delta^{p-2}+\frac{1}{2}\left(2\nabla\sqrt{\eta_R}\right)^2|h|^3|h|_\delta^{p-2}\\ &\le \frac{\tilde{\epsilon}}{2}\eta_R|\nabla h|^2|h|_\delta^{p-2}+2\tilde{\epsilon}\left(\nabla\sqrt{\eta_R}\right)^2|h|_\delta^p\end{aligned}$$

Combining above inequalities we obtain

(5.15)

$$\begin{aligned}\partial_t\int_{\mathbb{R}^n}\eta_R|h|_\delta^p\,\mathrm{d}x &\le \int_{\mathbb{R}^n}\left(\Delta\eta_R+C\tilde{\epsilon}p\left(\nabla\sqrt{\eta_R}\right)^2\right)|h|_\delta^p+p(C\tilde{\epsilon}-1)\eta_R|h|_\delta^{p-2}|\nabla h|^2\,\mathrm{d}x\\ &\le \frac{C(1+p)}{R^2}\int_{B_{2R}\setminus B_R}|h|_\delta^p\mathrm{d}x\end{aligned}$$

for $\tilde{\epsilon}<\frac{1}{C}$. After integrating with respect to t and taking the limit $\delta\to 0$ we see that the desired inequality holds true. □

Remark 5.4. The reason why above lemma only holds for $2\le p<\infty$ is because the term $-\eta_R p(p-2)|h|_{\tilde{\epsilon}}^{p-4}\langle\nabla_a h,h\rangle(g_{eucl}+h)^{ab}\langle\nabla_b h,h\rangle$ in line (5.13) is negative only for $p\ge 2$.

Now we can use Grönwall's Lemma to prove our theorem in the $p\ge 2$ case.

Proof of theorem 5.1 for $p\ge 2$. Choose $\tilde{\epsilon}>0$ and C_1 such that lemma 5.3 holds and consider the following quantity

$$A(t,R)=\sup_{x\in\mathbb{R}^n}\int_{\mathbb{R}^n}\eta_{R,x}(y)h^p(y,t)\,\mathrm{d}y. \qquad (5.16)$$

Centering (5.2) at x and integrating with respect to time we obtain

(5.17)

$$\int_{\mathbb{R}^n}\eta_{R,x}h^p(y,t)\,\mathrm{d}y\le\int_{\mathbb{R}^n}\eta_{R,x}h^p(y,0)\,\mathrm{d}y+\frac{C_1(1+p)}{R^2}\int_0^t\int_{B_{2R}(x)\setminus B_R(x)}h^p(y,t)\,\mathrm{d}y\,\mathrm{d}t.$$

Because we can cover $B_{2R}(x) \setminus B_R(x)$ by a finite number N of balls of radius R and furthermore this number only depends on the dimension n, we obtain

$$A(t,R) \leq A(0,R) + \frac{NC_1(1+p)}{R^2} \int_0^t A(t,R)\,\mathrm{d}t. \tag{5.18}$$

By Grönwall's inequality (see appendix) we deduce

$$A(t,R) \leq A(0,R) \exp\left(\frac{NC_1(1+p)}{R^2} t\right). \tag{5.19}$$

Then taking the limit $R \to \infty$ shows

$$\|h(\cdot,t)\|_{L^p(\mathbb{R}^n)} \leq \|h(\cdot,0)\|_{L^p(\mathbb{R}^n)} \tag{5.20}$$

□

Now we will generalize to the $1 \leq p < 2$ case. For this we will need the following L^p estimate, which is analog to the one stated in lemma 5.3.

Lemma 5.5. *There exists a $C_2 > 0$ such that for a solution $h \in C^{2,1}(\mathbb{R}^n \times [0,\infty))$ with $\|h\|_{L^\infty(\mathbb{R}^n \times [0,\infty))} < \frac{1}{2}$ to the Ricci DeTurck equation (3.4) the following estimate holds in the barrier sense for $1 \leq p \leq 2$*

$$\partial_t \int_{\mathbb{R}^n} \eta_R |h|^p \leq \frac{C_2}{R^2} \int_{B_{2R} \setminus B_R} |h|^p\,\mathrm{d}x + C_2 \int_{\mathbb{R}^n} \eta_R |\nabla h|^2\,\mathrm{d}x, \tag{5.21}$$

where C_2 depends on n and η only.

Remark 5.6. The main difficulty in proving theorem 5.1 for $1 \leq p < 2$ will be to bound $|\nabla h|^2$ in the above estimate.

Proof. Applying Cauchy-Schwarz to (5.5) we obtain

$$\partial_t |h|_\delta^p \leq \Delta |h|_\delta^p + p|h|_\delta^{p-2} \langle Q[h], h\rangle + |\nabla h|^2 |h|_\delta^{p-4} \left(p(2-p)|h|^2 - p|h|_\delta^2\right) \tag{5.22}$$

$$\leq \Delta |h|_\delta^p + p|h|_\delta^{p-2} \langle Q[h], h\rangle. \tag{5.23}$$

Multiplying by the cut-off function η_R, integrating by parts and discarding boundary terms we deduce

(5.24)

$$\begin{aligned}
\partial_t \int_{\mathbb{R}^n} \eta_R |h|_\delta^p &\leq \int_{\mathbb{R}^n} (\Delta \eta_R)\,|h|_\delta^p + \eta_R p |h|_\delta^{p-2} \langle Q_0[h] + \nabla Q_1[h], h\rangle\,\mathrm{d}x \\
&\leq \int_{\mathbb{R}^n} (\Delta \eta_R)\,|h|_\delta^p + \eta_R p |h|_\delta^{p-2} |h||Q_0[h]| - \langle Q_1[h], \nabla\left(\eta_R p |h|_\delta^{p-2} h\right)\rangle\,\mathrm{d}x \\
&\leq \int_{\mathbb{R}^n} (\Delta \eta_R)\,|h|_\delta^p + \eta_R p |h|_\delta^{p-2} |h||Q_0[h]| + |Q_1[h]|\Big(p|\nabla \eta_R||h|_\delta^{p-2}|h| \\
&\qquad + p\eta_R |h|_\delta^{p-2}|\nabla h| + \eta_R |p(p-2)||h|_\delta^{p-4}|h|^2|\nabla h|\Big)\,\mathrm{d}x.
\end{aligned}$$

Recalling the estimates of $Q_0[h]$ and $Q_1[h]$ in (5.9) and (5.10) respectively, we see that

$$\partial_t \int_{\mathbb{R}^n} \eta_R |h|_\delta^p \leq \int_{\mathbb{R}^n} (\Delta \eta_R)|h|_\delta^p + C\eta_R |h|_\delta^{p-2}|h||\nabla h|^2 + C|\nabla \eta_R||h|_\delta^{p-2}|h|^2|\nabla h| + C\eta_R |h|_\delta^{p-4}|h|^3|\nabla h|^2 \,\mathrm{d}x \tag{5.25}$$

$$\leq \int_{\mathbb{R}^n} \left(\Delta \eta_R + 2\left(\nabla \sqrt{\eta_R}\right)^2\right)|h|_\delta^p + C\eta_R |\nabla h|^2 \,\mathrm{d}x \tag{5.26}$$

$$\leq \frac{C}{R^2}\int_{B_{2R}\setminus B_R} |h|_\delta^p \,\mathrm{d}x + C\int_{\mathbb{R}^n} \eta_R |\nabla h|^2 \,\mathrm{d}x, \tag{5.27}$$

where we applied Young's inequality

$$|\nabla \eta_R||\nabla h| \leq \frac{1}{2}\eta_R |\nabla h|^2 + 2\left(\nabla \sqrt{\eta_R}\right)^2 \tag{5.28}$$

and used the assumption that $|h| < \frac{1}{2}$. Taking $\delta \to 0$ we obtain the desired result. □

We will now estimate $\|\nabla h\|_{L^2(\mathbb{R}^n \times (0,\infty))}$ in terms of $\|h_0\|_{L^2(\mathbb{R}^n)}$. By comparison to the standard heat equation $\partial_t u = \Delta u$ on $\mathbb{R}^n$ we expect such an estimate to exist: Multiplying the heat equation by u we have

$$\frac{1}{2}\partial_t u^2 = u\Delta u \tag{5.29}$$

Thus integrating by parts and rearranging we have

$$\int_0^t \int_{\mathbb{R}^n} |\nabla u|^2 \,\mathrm{d}x \,\mathrm{d}t = \frac{1}{2}\int_{\mathbb{R}^n} u(\cdot,0)^2 \,\mathrm{d}x - \frac{1}{2}\int_{\mathbb{R}^n} u(\cdot,t)^2 \,\mathrm{d}x \tag{5.30}$$

$$\leq \frac{1}{2}\int_{\mathbb{R}^n} u(\cdot,0)^2 \,\mathrm{d}x. \tag{5.31}$$

For the Ricci DeTurck equation (3.4) we can perform an analogous computation to deduce:

Lemma 5.7. *Let $\frac{1}{2} > \tilde{\epsilon} > 0$. Then for a solution $h \in C^{2,1}(\mathbb{R}^n \times [0,\infty))$ to the Ricci DeTurck equation (3.4) satisfying $\|h\|_{L^\infty(\mathbb{R}^n \times [0,\infty))} < \tilde{\epsilon}$ we have*

$$\partial_t \int_{\mathbb{R}^n} \eta_R |h|^2 \,\mathrm{d}x \leq (-\frac{1}{2} + C_3\tilde{\epsilon})\int_{\mathbb{R}^n} \eta_R |\nabla h|^2 \,\mathrm{d}x + \frac{C_3}{R^2}\int_{B_{2R}\setminus B_R} |h|^2 \,\mathrm{d}x, \tag{5.32}$$

where C_3 depends on n only.

Proof. Multiplying the Ricci DeTurck equation (3.4) by $\eta_R h$ and integrating by parts we obtain

$$\frac{1}{2}\partial_t \int_{\mathbb{R}^n} \eta_R h^2 \,\mathrm{d}x = \int_{\mathbb{R}^n} -\nabla(\eta_R h)\nabla h + \eta_R \langle h, Q_0[h]\rangle - \langle \nabla(\eta_R h), Q_1[h]\rangle \,\mathrm{d}x \tag{5.33}$$

$$\leq \int_{\mathbb{R}^n} -\eta_R |\nabla h|^2 + |\nabla \eta_R||h||\nabla h| + \eta_R |h||Q_0[h]| \tag{5.34}$$

$$+ \eta_R |\nabla h||Q_1[h]| + |\nabla \eta_R||h||Q_1[h]| \,\mathrm{d}x. \tag{5.35}$$

By Young's inequality we have

$$|\nabla \eta_R||h||\nabla h| = 2|\nabla \sqrt{\eta_R}||h|\sqrt{\eta_R}|\nabla h| \leq 2|\nabla \sqrt{\eta_R}|^2|h|^2 + \frac{1}{2}\eta_R |\nabla h|^2. \tag{5.36}$$

Applying estimates (5.9) and (5.10) for $Q_0[h]$ and $Q_1[h]$ respectively, we thus obtain

$$\frac{1}{2}\partial_t \int_{\mathbb{R}^n} \eta_R h^2 \,\mathrm{d}x \leq \int_{\mathbb{R}^n} -\frac{1}{2}\eta_R |\nabla h|^2 + 2|\nabla\sqrt{\eta_R}|^2|h|^2 + C\eta_R|h||\nabla h|^2 + C|\nabla\eta_R||h|^2|\nabla h| \,\mathrm{d}x \tag{5.37}$$

$$\leq \int_{\mathbb{R}^n} (-\frac{1}{2} + C\tilde{\epsilon})\eta_R|\nabla h|^2 \,\mathrm{d}x + 2\int_{\mathbb{R}^n} |\nabla\sqrt{\eta_R}|^2|h|^2 + C\tilde{\epsilon}\left(2|\nabla\sqrt{\eta_R}|^2|h|^2 + \frac{1}{2}\eta_R|\nabla h|^2\right) \mathrm{d}x \tag{5.38}$$

$$\leq (-\frac{1}{2} + C\tilde{\epsilon})\int_{\mathbb{R}^n} \eta_R|\nabla h|^2 \,\mathrm{d}x + \frac{C}{R^2}\int_{B_{2R}\setminus B_R} |h|^2 \,\mathrm{d}x \tag{5.39}$$

□

Using the above estimate we can bound the L^2 norm of $|\nabla h|$ over space and time.

Corollary 5.8. *There exists an $\frac{1}{2} > \tilde{\epsilon} > 0$ such that under the same conditions as in theorem 5.1 we have*

$$\int_0^\infty \int_{\mathbb{R}^n} |\nabla h|^2 \,\mathrm{d}x \leq 2\int_{\mathbb{R}^n} h_0^p \,\mathrm{d}x \tag{5.40}$$

for $1 \leq p \leq 2$.

Proof. We will prove the case $p = 2$ from which the result follows by the observation that

$$\int_{\mathbb{R}^n} h_0^2 \,\mathrm{d}x \leq \int_{\mathbb{R}^n} h_0^p \,\mathrm{d}x \tag{5.41}$$

for $\|h\|_{L^\infty(\mathbb{R}^n\times[0,\infty))} \leq 1$ and $1 \leq p \leq 2$. By theorem 5.1 for the case $p = 2$, which we proved above, we can pick $\tilde{\epsilon} > 0$ such that

$$\int_{\mathbb{R}^n} |h(x,t)|^2 \,\mathrm{d}x \leq \int_{\mathbb{R}^n} |h_0|^2 \,\mathrm{d}x \tag{5.42}$$

for all $t > 0$. Integrating the estimate from lemma 5.7 we have

$$\frac{1}{2}\int_{\mathbb{R}^n} \eta_R h^2(x,t) \,\mathrm{d}x - \frac{1}{2}\int_{\mathbb{R}^n} \eta_R h_0^2 \,\mathrm{d}x \leq (-\frac{1}{2} + C_3\tilde{\epsilon})\int_0^t \int_{\mathbb{R}^n} \eta_R|\nabla h|^2 \,\mathrm{d}x \tag{5.43}$$

$$+ \frac{C_3}{R^2}\int_0^t \int_{B_{2R}\setminus B_R} |h|^2 \,\mathrm{d}x. \tag{5.44}$$

Taking $\tilde{\epsilon} < \frac{1}{4C_3}$ and rearranging terms, we obtain the desired result by first taking the limit $R \to \infty$ and then $t \to \infty$. □

Having control of ∇h we now proceed to proving theorem 5.1 in the $1 \leq p < 2$ case.

Proof of theorem (5.1) for $1 \leq p < 2$. Take $\tilde{\epsilon} > 0$ small enough such that lemma 5.5 and corollary 5.8 hold. As previously define

$$A(t,R) = \sup_{x\in\mathbb{R}^n} \int_{\mathbb{R}^n} \eta_{R,x}(y)|h|^p(y,t) \,\mathrm{d}y. \tag{5.45}$$

Integrating (5.21) and covering $B_{2R}(x) \setminus B_R(x)$ by N balls of radius R as before we obtain

$$A(t,R) - A(0,R) \leq \frac{NC_2}{R^2} \int_0^t A(s,R)\,\mathrm{d}s + C_2 \int_0^t \int_{\mathbb{R}^n} \eta_R |\nabla h|^2. \tag{5.46}$$

Applying our $L^2(\mathbb{R}^n \times (0,\infty))$ bound of $|\nabla h|$ from corollary 5.8 and rearranging we deduce

$$A(t,R) \leq (2C_2+1)\,\|h_0\|^p_{L^p(\mathbb{R}^n)} + \frac{NC_2}{R^2} \int_0^t A(s,R)\,\mathrm{d}s. \tag{5.47}$$

Finally, applying Grönwall's inequality (see appendix) and taking $R \to \infty$ we obtain the desired result. □

5.2. L^∞ **decay rates.** In the following we will utilize the above L^p bounds to prove L^∞ decay rates for solutions h_t to the Ricci DeTurck flow (3.4). The rates we obtain are consistent with what one would expect by comparison with the initial value problem for standard linear heat equation $\partial_t u = \Delta u$ on $\mathbb{R}^n$: Assuming we can represent the solution as

$$u(x,t) = \int_{\mathbb{R}^n} K(x,t,y,0) u(y,0)\,\mathrm{d}y, \tag{5.48}$$

where $K(x,t,y,s) = (4\pi(t-s))^{-\frac{n}{2}} \exp\left(-\frac{|x-y|^2}{4(t-s)}\right)$ is the standard heat kernel on $\mathbb{R}^n$, we can use Young's inequality to estimate

$$\begin{aligned} \|h(\cdot,t)\|_{L^\infty(\mathbb{R}^n)} &\leq \|K\|_{L^{\frac{p}{p-1}}(\mathbb{R}^n)} \|u(\cdot,0)\|_{L^p(\mathbb{R}^n)} \\ &\leq \frac{C}{t^{\frac{n}{2p}}} \|u(\cdot,0)\|_{L^p(\mathbb{R}^n)} \end{aligned}$$

for some constant $C > 0$. We will show that the same result holds for Ricci DeTurck flow:

Lemma 5.9. *There exists constants $\epsilon' = \epsilon'(n) > 0$ and $C' = C'(n) > 0$ such that for a solution h_t to the Ricci DeTurck equation (3.4) satisfying (i) $\|h_0\|_{L^\infty(\mathbb{R}^n)} < \epsilon'$ and (ii) $\|h_0\|_{L^p(\mathbb{R}^n)} < \infty$ for some $1 \leq p < \infty$, we have*

$$\|h_t\|_{L^\infty(\mathbb{R}^n)} < \|h_0\|_{L^p(\mathbb{R}^n)} \frac{C'}{t^{\frac{n}{2p}}}, \qquad t > 0. \tag{5.49}$$

Before we prove above lemma we will state a useful interpolation inequality.

Lemma 5.10. *Let $f \in L^p(\mathbb{R}^n)$ for some $p \in [1,\infty)$ and $Df \in L^\infty(\mathbb{R}^n)$. Then there exists a constant $C(n,p)$ such that*

$$\|f\|_{L^\infty(\mathbb{R}^n)} \leq C(n,p) \|f\|^{\frac{p}{n+p}}_{L^p(\mathbb{R}^n)} \|Df\|^{\frac{n}{n+p}}_{L^\infty(\mathbb{R}^n)}. \tag{5.50}$$

In particular, we can choose $C(n,p) = \left(\frac{(p+1)\cdots(p+n)}{\omega_n n!}\right)^{\frac{1}{n+p}}$.

Proof. Let $x_0 \in \mathbb{R}^n$ and w.l.o.g. assume $f(x_0) > 0$. If we set $r_{x_0} = \frac{f(x_0)}{\|Df\|_{L^\infty(\mathbb{R}^n)}}$ we have for any x such that $|x - x_0| \leq r_{x_0}$

$$|f(x)| \geq \left| f(x_0) - \|Df\|_{L^\infty(\mathbb{R}^n)} |x - x_0| \right| \tag{5.51}$$

Integrating we get

$$\int_{\mathbb{R}^n} |f(x)|^p \,\mathrm{d}^n x \geq \int_{|x-x_0|\leq r_{x_0}} \left| f(x_0) - \|Df\|_{L^\infty(\mathbb{R}^n)} |x-x_0| \right|^p \,\mathrm{d}^n x \tag{5.52}$$

$$\geq n\omega_n \int_0^{r_{x_0}} r^{n-1} \left(f(x_0) - \|Df\|_{L^\infty(\mathbb{R}^n)} r \right)^p \,\mathrm{d}r \tag{5.53}$$

$$\geq n\omega_n r_{x_0}^n f(x_0)^p \left(\int_0^1 s^{n-1}(1-s)^p \,\mathrm{d}s \right), \tag{5.54}$$

where in the last line we used the substitution $r = r_{x_0} s$ and ω_n denotes the volume of the unit ball in n dimensions. After evaluating the integral, re-substituting for r_{x_0} and rearranging the last inequality we obtain the desired result. □

We can now prove lemma 5.9.

Proof of lemma 5.9. Choose $\epsilon > 0, C > 0$ as in section 3.2 and $\tilde{\epsilon} > 0, \tilde{C} > 0$ as in theorem 5.1. Take $\epsilon' = \frac{1}{C}\min(\tilde{\epsilon}, \epsilon)$. Then by estimate (3.8) we have $\|h_t\|_{L^\infty(\mathbb{R}^n)} < \min(\tilde{\epsilon}, \epsilon)$ for all $t \geq 0$. Thus we can apply theorem 5.1 in conjunction with the above lemma 5.10 to deduce

$$\|h_t\|_{L^\infty(\mathbb{R}^n)} \leq C(n,p)\tilde{C}^{\frac{p}{n+p}} \|h_0\|_{L^p(\mathbb{R}^n)}^{\frac{p}{n+p}} \|Dh_t\|_{L^\infty(\mathbb{R}^n)}^{\frac{n}{n+p}}, \tag{5.55}$$

Applying the derivative estimate (3.8) we deduce that for $t > 0$

$$\sup_{x\in\mathbb{R}^n} |Dh_t(x)| \leq \frac{CR}{t^{\frac{1}{2}}} \|h_0\|_{L^\infty(\mathbb{R}^n)}. \tag{5.56}$$

Combining the above inequalities we therefore obtain

$$\|h_t\|_{L^\infty(\mathbb{R}^n)} \leq C(n,p)\tilde{C}^{\frac{p}{n+p}} (CR\epsilon')^{\frac{n}{n+p}} \|h_0\|_{L^p(\mathbb{R}^n)}^{\frac{p}{n+p}} t^{-\frac{n}{2(n+p)}}. \tag{5.57}$$

As noted above $\|h_t\|_{L^\infty(\mathbb{R}^n)} < \epsilon$ for all $t \geq 0$, so we may start the flow from $\frac{t}{2}$ and reapply the estimate (3.8)

$$|Dh_t(x)| \leq \frac{CR}{\left(\frac{t}{2}\right)^{\frac{1}{2}}} \left\| h_{\frac{t}{2}} \right\|_{L^\infty(\mathbb{R}^n)}. \tag{5.58}$$

Using (5.58) and (5.55) recursively we can successively obtain better decay rates for h. Let (C_i, α_i, β_i) be such that after the i-th iteration we have $|h_t(x)| \leq C_i t^{\alpha_i} \|h_0\|_{L^p(\mathbb{R}^n)}^{\beta_i}$. Then $(C_1, \alpha_1, \beta_1) = \left(C(n,p)\tilde{C}^{\frac{p}{n+p}} (CR\epsilon')^{\frac{n}{n+p}}, -\frac{n}{2(n+p)}, \frac{p}{n+p} \right)$ and at the i-th recursion step we obtain

$$\begin{aligned} |Dh_t(x)| &\leq \frac{CR}{(\frac{t}{2})^{\frac{1}{2}}} \left\| h_{\frac{t}{2}} \right\|_{L^\infty(\mathbb{R}^n)} \\ &\leq \frac{2^{\frac{1}{2}} RC}{t^{\frac{1}{2}}} C_i \left(\frac{t}{2} \right)^{\alpha_i} \|h_0\|_{L^p(\mathbb{R}^n)}^{\beta_i} \\ &\leq RCC_i 2^{\frac{1}{2}-\alpha_i} t^{\alpha_i - \frac{1}{2}} \|h_0\|_{L^p(\mathbb{R}^n)}^{\beta_i} \end{aligned} \tag{5.59}$$

and therefore

$$\|h_t\|_{L^\infty(\mathbb{R}^n)} \leq C(n,p)\tilde{C}^{\frac{p}{n+p}} \left(2^{\frac{1}{2}-\alpha_i} RCC_i \right)^{\frac{n}{n+p}} t^{\frac{n}{n+p}(\alpha_i - \frac{1}{2})} \|h_0\|_{L^p(\mathbb{R}^n)}^{\frac{p}{n+p}+\beta_i \frac{n}{n+p}}. \tag{5.60}$$

From above we can read off the following recursion relations for α_i, β_i and C_i:

$$C_{i+1} = C(n,p)\tilde{C}^{\frac{p}{n+p}}(2^{\frac{1}{2}-\alpha_i}RCC_i)^{\frac{n}{n+p}} \tag{5.61}$$

$$\alpha_{i+1} = \frac{n}{n+p}\left(\alpha_i - \frac{1}{2}\right) \tag{5.62}$$

$$\beta_{i+1} = \frac{p}{n+p} + \beta_i\frac{n}{n+p} \tag{5.63}$$

We then note that $\alpha_i \to -\frac{n}{2p}$, $\beta_i \to 1$ and $C_i \to C_* := 2^{\frac{n(n+p)}{2p^2}}\,(C(n,p))^{\frac{n+p}{p}}\,(RC)^{\frac{n}{p}}$ as $i \to \infty$. Using the expression for $C(n,p)$ we can bound $C_* \leq C'(n)$, for $C'(n)$ a constant depending on n only. Thus the desired result holds true. □

We also get the following corollary of the above lemma.

Corollary 5.11. *Under the same conditions as in lemma 5.9 we have for any $k \in \mathbb{N}_0$ and multiindex $\alpha \in \mathbb{N}_0^n$*

(5.64)
$$\sup_{x\in\mathbb{R}^n}\sup_{t>0} t^{\frac{n}{2p}}|(t^{\frac{1}{2}}\nabla)^\alpha(t\partial_t)^k(g-g_{eucl})(x,t)| \leq \|h_0\|_{L^p(\mathbb{R}^n)}\,C'(n)R^{|\alpha|+k}(|\alpha|+k)!,$$

where $R > 0$ is as in (3.8) and $C'(n)$ is a constant depending on n only.

Proof. Apply the derivative estimate (3.8) at time $\frac{t}{2}$ with the bound on $\left\|h_{\frac{t}{2}}\right\|_{L^\infty(\mathbb{R}^n)}$ from above lemma 5.9. □

Combining the results from [KL12, Theorem 4.3], theorem 4.5, theorem 5.1 and the above corollary 5.11, we have proven theorem 1.2.

6. Positive Scalar rigidity

In this section we will prove the scalar rigidity theorem 1.1 by evolving the metric via the Ricci DeTurck flow (3.4). The decay rates obtained in corollary 5.11 show that the scalar curvature $|R| \lesssim |\nabla^2 g|$ will decay at a rate of order $O(t^{-\frac{n}{2p}-1})$. Because the scalar curvature also satisfies the following super heat equation under Ricci DeTurck flow

$$\partial_t R_{g_t} = \Delta_{g_t}R_{g_t} - \partial_{X(g_t)}R_{g_t} + 2|Ric(g_t)|^2_{g_t}, \tag{6.1}$$

we expect R to decay at a rate at most of order $O(t^{-\frac{n}{2}})$, which is the L^∞ decay rate of the heat kernel on $\mathbb{R}^n$. For $p < \frac{n}{n-2}$ this leads to a contradiction, because the scalar curvature would have to decay faster than equation (6.1) allows. In this case we will deduce that the metric must have been flat.

The new ingredient in this section is Perelman's Harnack Inequality, which will be used to prove a lower bound for the heat kernel on a Ricci flow background. Because in the non-compact case Perelman's Harnack Inequality requires uniform curvature bounds, which we do not have at $t = 0$, we will first run Ricci DeTurck flow for a short time $t_0 > 0$ to obtain uniform curvature bounds. Then we evolve the metric via the Ricci flow from time t_0 onwards and apply Perelman's Harnack Inequality. The only technical difficulty is to show that the scalar curvature remains positive at early times, because on a non-compact manifold without any curvature bounds we cannot apply the maximum principle to the super heat equation (6.1).

6.1. **General Setup.** For the rest of this section we will fix an $\epsilon > 0$ and $C > 0$ such that theorem 1.2 hold. We will also assume that we are given a smooth metric g that satisfies $R_g \geq 0$, $\|g - g_{eucl}\|_{L^\infty(\mathbb{R}^n)} < \epsilon$ and $\|g - g_{eucl}\|_{L^p(\mathbb{R}^n)} < \infty$ for some $p \in [1, \infty)$.

6.2. **Nonnegativity of Scalar curvature.** Evolving the metric g via Ricci DeTurck flow, we obtain a family of metrics $(g_t)_{t\geq 0}$ solving (3.3) starting from initial data $g_0 = g$. By theorem 4.1 this solution is smooth on $\mathbb{R}^n \times [0, \infty)$, in particular all derivatives of the solution converge locally to the initial data as $t \to 0$. In the lemma below we will prove that the scalar curvature $R(g_t)$ remains non-negative at all times $t \geq 0$.

Lemma 6.1. *Let g be as above. Then the scalar curvature remains positive in the Ricci DeTurck flow starting from g.*

Proof. We can apply [Bam16, Lemma 4], because the assumption that $g - g_{eucl}$ is compactly supported was only used to prove that the first and second derivatives of g_t vary continuously as $t \to 0$. By parabolic dilations, [Bam16, Lemma 4] implies that for every $\delta > 0$ there is a $\tau = \tau(\delta)$ such that the following is true: Assume that $R(g_0) > a$ on $B(o, r)$ for some $a \in \mathbb{R}$. Then the solution $(g_t)_{t\geq 0}$ to the Ricci DeTurck flow equation (3.4) satisfies $R(o, t) > a - \frac{\delta}{r^2}$ for all $t \in [0, \tau r^2]$. Since we can take any $a < 0$ and $r > 0$ the result follows. □

Remark 6.2. We did not use the condition $\|g - g_{eucl}\|_{L^p(\mathbb{R}^n)} < \infty$ in above lemma.

Remark 6.3. One can show using [Bam16, Lemma 4] that there are constants $\epsilon > 0$ and $C > 0$ such that no metric g on $B_1(0) \subset \mathbb{R}^n$ exists, such that $\|g - g_{eucl}\|_{L^\infty(B_1(0))} < \epsilon$ and the scalar curvature $R_g > C$ everywhere on $B_1(0)$.

6.3. **Lower Heat Kernel bounds on Ricci flow background.** Fix $t_0 > 0$ and let $\tilde{g}_{t_0+t} = (\Phi_{t_0+t})^* g_{t_0+t}$, $t \geq 0$ be the corresponding Ricci flow starting from g_{t_0} (see section 3.3). Because $(\tilde{g}_{t_0+t})_{t\geq 0}$ and $(g_{t_0+t})_{t\geq 0}$ are related by diffeomorphisms, we obtain by corollary 5.11 the following uniform curvature bounds

$$|R_{\tilde{g}_t}|_{\tilde{g}_t}, |Rc_{\tilde{g}_t}|_{\tilde{g}_t}, |Rm_{\tilde{g}_t}|_{\tilde{g}_t} < \frac{C_2 \|g - g_{eucl}\|_{L^p(\mathbb{R}^n)}}{(t_0 + t)^{1+\lambda}}, \tag{6.2}$$

where $\lambda = \frac{n}{2p}$ and C_2 is a constant depending on C and n. These bounds allow us to estimate $\tilde{g}_{t_0+t}$ in terms of $\tilde{g}_{t_0}$ using the Ricci flow equation (3.9)

$$e^{-C_3}\tilde{g}_{t_0} \leq \tilde{g}_{t_0+t} \leq e^{C_3}\tilde{g}_{t_0}, \qquad t \geq 0, \tag{6.3}$$

where $C_3 = \frac{C_2\|g-g_{eucl}\|_{L^p(\mathbb{R}^n)}}{\lambda t_0^\lambda}$. On the Ricci flow background the scalar curvature satisfies a super heat equation related to (6.1)

$$\partial_t R_{\tilde{g}_{t_0+t}} = \Delta_{\tilde{g}_{t_0+t}} R_{\tilde{g}_{t_0+t}} + 2|Ric(\tilde{g}_{t_0+t})|^2_{\tilde{g}_{t_0+t}}, \quad t \geq 0. \tag{6.4}$$

In order to analyse the above equation we need lower bounds on the heat kernel $K_{\tilde{g}}(x, t; y, s)$ of the linear heat equation

$$\partial_t u = \Delta_{\tilde{g}_{t_0+t}} u, \qquad t \geq 0, \tag{6.5}$$

on the Ricci flow background $(\tilde{g}_{t_0+t})_{t\geq 0}$. Our work will rely on Perelman's Harnack Inequality (see [Per02, Section 9]), the basic setup of which we will recap here. Let

$x, y \in \mathbb{R}^n$ and $0 < s < t < T$, then the $\mathcal{L}$-length of a curve $\gamma : [s,t] \to \mathbb{R}^n$ is defined as

$$\mathcal{L}(\gamma) := \int_s^t \sqrt{t-t'}\Big(R(\gamma(t'),t') + |\dot{\gamma}(t')|^2_{t'}\Big)\,\mathrm{d}t' \tag{6.6}$$

The reduced distance between (x,t) and (y,s) is then defined as

$$l_{(x,t)}(y,s) := \frac{1}{2\sqrt{t-s}} \inf\{\mathcal{L}(\gamma) | \quad \gamma : [s,t] \to \mathbb{R}^n \quad \text{between } (x,t) \text{ and } (y,s)\} \tag{6.7}$$

It is well known that for Ricci flow on a closed manifold we may bound the heat kernel below using the reduced distance (see [ChII, Lemma 16.49]). We will now show that the same holds true in our non-compact setting.

Lemma 6.4. *In the same notation as above we have for $t > s \geq 0$*

$$K_{\tilde{g}}(x,t,y,s) \geq \frac{1}{(4\pi(t-s))^{\frac{n}{2}}} \exp\left(-l_{(x,t)}(y,s)\right). \tag{6.8}$$

Proof. Because of the uniform curvature bounds for $(\tilde{g}_{t_0+t})_{t\geq 0}$ on $\mathbb{R}^n \times [0,\infty)$ by (6.2), Perelman's comparison geometry for $\mathcal{L}$ still holds true [ChI, pp.322] . The curvature bounds in conjunction with the bilipshitz bounds (6.3) ensure that the weak maximum principle for the heat equation on $(\mathbb{R}^n, (\tilde{g}_{t_0+t})_{t\geq 0})$ holds true by [ChII, pp. 140]. Therefore the proofs of [ChII, Lemma 16.48] and [ChII, Lemma 16.49] carry over to our non-compact setting. □

We proceed by bounding the reduced distance $l_{(x,t)}(y,s)$

$$l_{(x,t)}(y,s) \leq \frac{1}{2\sqrt{t-s}} \int_s^t \sqrt{t-t'}\left(\frac{C_2\,\|g - g_{eucl}\|_{L^p(\mathbb{R}^n)}}{(t_0+t')^{1+\lambda}} + e^{C_3}|\dot{\gamma}(t')|^2_{\tilde{g}_{t_0}}\right)\mathrm{d}t' \tag{6.9}$$

$$\leq \|g - g_{eucl}\|_{L^p(\mathbb{R}^n)} \frac{C_2}{2} \int_s^t \frac{1}{(t_0+t')^{1+\lambda}}\,\mathrm{d}t' + \frac{e^{C_3}}{3}\frac{|x-y|^2}{t-s} \tag{6.10}$$

$$\leq \frac{C_2}{2\lambda}\frac{\|g - g_{eucl}\|_{L^p(\mathbb{R}^n)}}{(t_0+s)^{\lambda}} + \frac{e^{C_3}}{3}\frac{|x-y|^2}{t-s}. \tag{6.11}$$

We may summarize the above in the following lemma

Lemma 6.5. *In the notation from above, let $(g_t)_{t\geq 0}$ be a solution to the Ricci DeTurck equation (3.3) starting from $g_0 = g$ and let $(\tilde{g}_{t_0+t})_{t\geq 0}$ be the corresponding Ricci flow starting from g_{t_0}. Then for $t > s \geq 0$ we have*

$$K_{\tilde{g}}(x,t,y,s) \geq \exp\left(-\frac{C_2}{2\lambda}\frac{\|g - g_{eucl}\|_{L^p(\mathbb{R}^n)}}{(t_0+s)^{\lambda}}\right)\frac{1}{(4\pi(t-s))^{\frac{n}{2}}}\exp\left(-\frac{e^{C_3}}{3}\frac{|x-y|^2}{t-s}\right), \tag{6.12}$$

where C_2 depends on C and n, $C_3 = \frac{C_2\|g-g_{eucl}\|_{L^p(\mathbb{R}^n)}}{\lambda t_0^{\lambda}}$ and $\lambda = \frac{n}{2p}$.

Proof. See above. □

6.4. **Proof of positive scalar curvature rigidity.** Now we proceed to prove the main theorem of this section.

Proof of theorem 1.1. Let $(g_t)_{t\geq 0}$ be the Ricci DeTurck flow starting from $g_0 = g$ as above. Assume that at some point $(x_0,t_0) \in R^n \times (0,\infty)$ we have $R_0 := R(g_{t_0})(x_0) > 0$. By translation we may assume without loss of generality that

$x_0 = o$. Then consider the Ricci flow $(\tilde{g}_{t_0+t})_{t\geq 0}$ starting from the initial metric g_{t_0}. Pick $\delta > 0$ such that $R(\tilde{g}_{t_0}) \geq \frac{R_0}{2}$ on $B_o(\delta)$. Then from (6.4) and lemma 6.5 we have for $t \geq 1$

$$R(\tilde{g}_{t_0+t})(o) \geq \int_{\mathbb{R}^n} K_{\tilde{g}}(0,t,y,0) R(\tilde{g}_{t_0})(y)\, \mathrm{d}V_{\tilde{g}_{t_0}} \tag{6.13}$$

$$\geq \frac{R_0}{2} \int_{B_o(\delta)} K_{\tilde{g}}(0,t,y,0)\, \mathrm{d}V_{\tilde{g}_{t_0}} \tag{6.14}$$

$$\geq \frac{R_0}{2} \int_{B_o(\delta)} \exp\left(-\frac{C_3}{2}\right) \frac{1}{(4\pi t)^{\frac{n}{2}}} \exp\left(-\frac{e^{C_3}}{3}\frac{|y|^2}{t}\right) \mathrm{d}V_{\tilde{g}_{t_0}} \tag{6.15}$$

$$\geq \frac{C_4}{t^{\frac{n}{2}}}, \tag{6.16}$$

where $C_4 > 0$ is a constant independent of t. For $1 \leq p < \frac{n}{n-2}$ this contradicts the curvature decay rates (6.2) and we deduce that $R(g_t) = 0$ for all $t \geq 0$. Therefore $|Ric(g_t)| = 0$ for $t \geq 0$ by equation (6.4). Because Ricci DeTurck flow is related to Ricci flow by a family of diffeomorphisms and Ricci flow is stationary for $Ric = 0$, we deduce by the curvature decay rates (6.2) that our initial metric g must have been flat. □

In the borderline case case $p = \frac{n}{n-2}$, $n \geq 3$ we can prove that the scalar curvature $R(g_t)$ becomes bounded in L^1 for any $t > 0$:

Lemma 6.6. *Let g be a smooth metric as in theorem 1.1 for $p = \frac{n}{n-2}$ and let $(g_t)_{t\geq 0}$ be a solution to the Ricci DeTurck flow (3.4) starting from the initial data $g_0 = g$. Then we have the following estimate for $t_0 > 0$*

$$\int_{\mathbb{R}^n} R(g_{t_0})(x)\, \mathrm{d}x < C_5 \left\|g - g_{eucl}\right\|_{L^p(\mathbb{R}^n)} \exp\left(\frac{C_2}{2\lambda} \frac{\left\|g - g_{eucl}\right\|_{L^p(\mathbb{R}^n)}}{t_0^{\lambda}}\right), \tag{6.17}$$

where C_2, C_5 are constants depending on n and C only.

Proof. As before we have

$$R(g_{t_0+t})(o) \geq \int_{\mathbb{R}^n} \frac{1}{(4\pi t)^{\frac{n}{2}}} \exp\left(-\frac{C_3}{2}\right) \exp\left(-\frac{e^{C_3}}{3}\frac{|x|^2}{t}\right) R(g_{t_0})(x)\, \mathrm{d}V_{g_{t_0}}. \tag{6.18}$$

Recalling our curvature estimate

$$R(g_{t_0+t})(o) < \frac{C_2 \left\|g - g_{eucl}\right\|_{L^p(\mathbb{R}^n)}}{(t_0+t)^{1+\lambda}} \tag{6.19}$$

gives

$$C_2(4\pi)^{\frac{n}{2}} \left\|g - g_{eucl}\right\|_{L^p(\mathbb{R}^n)} \exp\left(\frac{C_3}{2}\right) > \int_{\mathbb{R}^n} \exp\left(-\frac{e^{C_3}}{3}\frac{|x|^2}{t}\right) R(g_{t_0})(x)\, \mathrm{d}V_{g_{t_0}}, \tag{6.20}$$

since $1 + \lambda = 1 + \frac{n}{2p} = \frac{n}{2}$ in the borderline case $p = \frac{n}{n-2}$. By (3.8) we have

$$\left\|g_{t_0} - g_{eucl}\right\|_{L^\infty(\mathbb{R}^n)} < C\epsilon, \tag{6.21}$$

so for $\epsilon > 0$ suitably small

$$(1 + C\epsilon)^{-n} \mathrm{d}V_{g_{eucl}} \leq \mathrm{d}V_{g_{t_0}} \leq (1 + C\epsilon)^n \mathrm{d}V_{g_{eucl}}. \tag{6.22}$$

Thus by the monotone convergence theorem we can take the limit $t \to \infty$ in (6.20) and obtain the desired result. □

Appendix

Grönwall's Inequality 6.7. *Let u and f be continuous and non-negative functions defined on $I = [\alpha, \beta]$, and let $n(t)$ be a continous, positive, nondecreasing function defined on I; then*

$$u(t) \leq n(t) + \int_\alpha^t f(s)u(s)\,\mathrm{d}s, \quad t \in I, \tag{6.23}$$

implies that

$$u(t) \leq n(t) \exp\left(\int_\alpha^t f(s)\,\mathrm{d}s\right), \quad t \in I. \tag{6.24}$$

Proof. See [Pach98], theorem 1.3.1. □
